Abstract

Node overlap removal is often a necessary step in many scenarios including laying out a graph, or visualizing a tag cloud. Our contribution is a new overlap removal algorithm that iteratively builds a Minimum Spanning Tree on a Delaunay triangulation of the node centers and removes the node overlaps by "growing" the tree. The algorithm is simple yet it produces high quality layouts and usually runs several times faster than the widely used PRISM algorithm.

Categories and Subject Descriptors (according to ACM CCS): I.3.3 [Computer Graphics]: Picture/Image Generation—Line and curve generation

1. Introduction

A configuration with overlapped nodes often appears after applying a graph layout algorithm [Tan07]. To remedy this an overlap removal algorithm is usually applied. The algorithm PRISM [GH10] is widely used for this purpose. Our contribution is a simple algorithm that we call Growing Tree, or GTree further on, running faster than PRISM and producing outputs of comparable quality. To make the comparison with PRISM easier we implemented GTree in the open source graph visualization software Graphviz, where PRISM is the default overlap removal algorithm.

There is vast research on node overlap removal. Some layout methods have been extended to take the node sizes into account [FS04,F91,LYC09,LEN05,WM95,DM06]. Another possibility is to solve the problem by a post-processing step, for which many different approaches exist [LMR98,GN98,JAG+08,SSS’12,HLG07,GNCNT13,GNSRP’13]. The idea of another set of algorithms is to define pairwise node constraints and translate the nodes to satisfy the constraints [MLE95,HIMF02,MSM93,HLO3]. These methods consider horizontal and vertical problems separately, which may lead to a distorted aspect ratio [GH10]. In [DMS06] the overlap removal is reduced to a quadratic problem and is solved efficiently in \(O(n \log n)\) steps. According to [GH10], the quality and the speed of the method of [DMS06] is very similar to the ones of PRISM.

In PRISM [GH10,H09], a Delaunay triangulation on the node centers is used as the starting point of an iterative step.

Then a stress model for node overlap removal is built on the edges of the triangulation and the stress function of the model is minimized using an iterative linear system solver. The high level structure of GTree is similar to PRISM. We also start with a Delaunay triangulation, but we use it in a different manner.

2. GTree Algorithm

Let us give some definitions. An input to GTree is a set of nodes \(V\), where each node \(i \in V\) is represented by a rectangle \(B_i\) with the center \(p_i\). We assume that for different \(i, j \in V\) the centers \(p_i, p_j\) are different too. If this is not the case, we randomly shift the nodes by tiny offsets. We denote by \(D\) a Delaunay triangulation of the set \(\{p_i : i \in V\}\), and let \(E\) be the set of edges of \(D\).

On a high level, a step of our method proceeds as follows. First we calculate the triangulation \(D\), then we define a cost function on \(E\) and build a minimum cost spanning tree on \(D\) for this cost function. Finally, we let the tree "grow". The steps are repeated until there are no more overlaps. The last several steps are slightly modified. Now we explain the algorithm in more detail.

We define the cost function \(c\) on \(E\) in such a way that the larger the overlap on an edge becomes, the smaller the cost of this edge comes to be. Let \((i, j) \in E\). If the rectangles \(B_i\) and \(B_j\) do not overlap then \(c(i, j) = \text{dist}(B_i, B_j)\), that is the distance between \(B_i\) and \(B_j\). Otherwise, for a real number \(t\)
We can now resolve the overlaps by growing the tree, similar to the growth of a tree in the nature. Starting from the
root node of $T$ we grow the edges adjacent to the root, then continue to its children recursively. Let $p^r_i$ be the vector
of new positions and $p^r_i = p_i$ for the root $r$. Then growing an edge $(i, j) \in E$ at node $i$ yields $p^r_j = p^r_i + t_{ij}(p_j - p_i)$ for $j$.

Different roots produce the same results modulo a translation of the plane by a vector. We iterate the high level step,
starting from finding a Delaunay triangulation, then building a minimum spanning tree on it, and growing the tree (see
Fig 2), while an overlap along an edge of the triangulation is found.

When there are no overlaps on edges of the triangulation, as noticed in [GH10], overlaps are still possible. We follow
the same idea as PRISM and modify the iteration step. In addition to calculating the Delaunay triangulation we run a
sweep-line algorithm to find all overlapping pairs and augment the Delaunay graph $D$ with each such pair. As a conse-
quence, the resulting minimum spanning tree contains non
Delaunay edges catching the overlaps, and the rest of the
overlaps get resolved. This stage usually requires much less
time than the previous one.

**Comparing GTree and PRISM:** We run comparisons by
using edge length dissimilarity, $\sigma_{\text{edge}}$ [GH10], Procrustean
similarity transformation, $\sigma_{\text{sym}}$ [BG05], and calculating the
area of the graph bounding box. GTree always needs more
area than PRISM, but the two other quality measures are
close. In Fig. 3, we compare the total CPU time using the
same set of graphs as in PRISM [GH10,GN00] on a PC with
Linux and an Intel Core i7-2600K CPU @ 3.40GHz. Overall
GTree seems to be a good alternative to PRISM, due to its
simplicity.
